(54) Graphical configuration of data processing networks.

(57) A computer system and method for configuring communication and database networks in a user friendly graphical environment and automatically generating related configuration files. In a preferred practice, the user defines multiple network workstation nodes using icons (13), specifies (12) the resources associated with each icon, and defines connections between icons using specified protocol constraints, and the computer validates the network so defined, and generates the associated configuration files for the respective workstation nodes. The workstations have requester/server capability for communication and database network operation. The configuration files are preferably distributed and installed using the network resources. The network topology information so created can be stored, retrieved and modified as necessary to suit the needs of an evolving network.

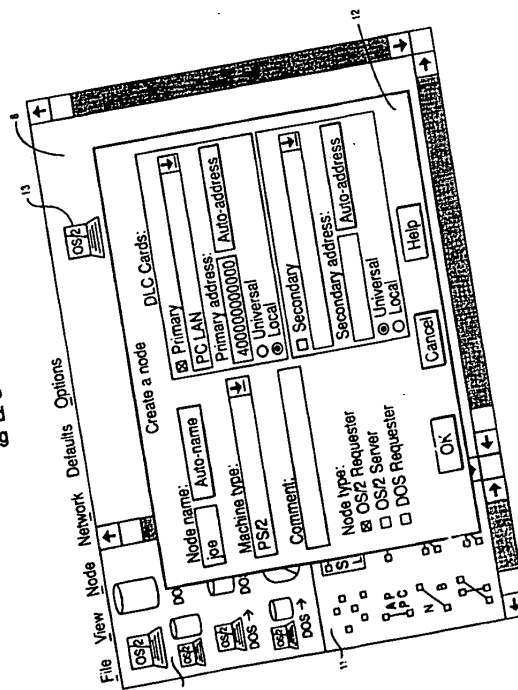

FIG. 2

EP 0 490 624 A2

Jouve, 18, rue Saint-Denis, 75001 PARIS

The present invention relates generally to the configuration of data processing networks. More particularly, the invention defines a computer system and method of use for graphically defining a network and deriving configuration parameters for the node terminals of the network.

The configuration of multiple personal computers and workstations into networks, and with increasing frequency hierarchically ordered sets of networks, provides communication and information retention resources not available to independent workstations. Consequently, there exists a significant trend toward network use of workstations. Unfortunately, the industry remains fluid as to network protocols and includes as prevailing and representative communication networks Ethernet, Token-Ring, PC Network (trademark of IBM Corporation), IEEE 802.2, Netbios, X.25, SDLC, and APPC. Furthermore, given that the network users expect database capability in addition to communication capability, database requester and database server functions in workstations and bridges are similarly subject to particularization in the course of defining the composite network. Network definition is even further complicated by the common use of multiple communication boards interfacing distinctly differing networks in one or more of the node workstations.

The configuration of the individual workstations into networks to match communication and database protocols has routinely been the responsibility of a network administrator. As the number of network nodes, the number of internetwork bridges and variety of network protocols increase, it has become apparent that the network administrator needs computer assistance to define and revise networks, and to generate the appropriate configuration files for each of the workstations within the network.

U. S. Patent 4,864,492 recognized the need for assisting a network administrator. The patent thus provides a system and method for applying a knowledge based expert system to the creation of configuration parameters individualized to the workstations of complex networks. The knowledge of the expert system is used to provide a menu and control the selections available to the network administrator.

Another reference of some relevance is U. S. Patent 4,942,540. The subject matter in that patent relates to creating and selecting a communication path between a user's terminal and a destination terminal by selecting the communication parameters from a scrollable menu. Graphical representations of the terminals and path are depicted in response to different menu selections. Though network usage is noted, the teachings relate to the definition of a communication path between a pair of terminals, namely, between the user's local terminal and a single remote terminal.

The increased prevalence of networks with greater

numbers of nodes, diverse communication protocols, and different functional modes, together with the bridging of multiple local area networks into wide area networks, has created an environment in which there is a need for graphically depicting networks having numerous nodes, for interactively specifying the connecting protocols between the nodes, and for automating the configuration of each workstation in the network based upon its capabilities, the modes of operation defined for the workstation, and the protocols specified for such modes of operation.

The present invention provides a system and method of operation by which a network administrator can, as a first feature, graphically depict a network by defining a multiplicity of workstation nodes with respective hardware and operating system characteristics, can then define the protocols of the communication paths between the network workstations, and based upon such network of workstations and communication path constraints can thereafter generate configuration parameters for the operating systems of the respective workstations. A further variation of the invention allows the configuration manager to switch the modes of operation defined for the network, for example between a communication mode and a database mode, and thereupon selectively redefine the workstation and communication path characteristics for the combined modes of operation. A further refinement of the invention provides for the automated distribution of such network workstation configuration parameters as an element of configuring the network depicted by graphical representation. The network parameters are capable of being stored, recalled, redefined and retransmitted with relative ease by graphical manipulation.

The present invention may be embodied in a system comprising a known computer set up to operate according to a novel program.

These and other features of the invention will be understood and appreciated with greater specificity upon considering the detailed description of a preferred embodiment given by way of example only and with reference to the accompanying drawings.

Brief Description of the Drawings

Fig. 1 schematically depicts a network environment relating to a use of the invention.

Fig. 2 schematically depicts a video display image of a network node and a related dialog window.

Figs. 3 and 4 schematically depict video display images at differing stages of network definition.

Fig. 5 schematically illustrates a video display image of the network including a dialog window suitable to save network configuration information.

Figs. 6-20 contain flow diagrams representing different functions available to a user of the present invention.

Fig. 1 schematically depicts an extended network, which has been simplified for purposes of illustrating the principles of the invention, composed of two local area networks, individually having different forms of workstations, which are joined through a network bridge. The composite network, often referred to as a wide area network (WAN), includes a token-ring local area network (LAN) at 1 and a PC Network LAN (PC Network is a trademark of IBM Corporation), generally at 2, communicating through network bridge 3. Token-ring LAN 1 is shown to have three nodes, including database and LAN requester node 4, database requester node 6, and database and LAN server node 7. The nodes are preferably configured with IBM brand PS/2 (trademark of IBM Corporation) workstations having appropriate OS/2 (trademark of IBM Corporation) operating system programs for accomplishing the prescribed functions. LAN 2 is shown to have a single node database requester, again preferably configured with a PS/2 workstation having the appropriate database requester OS/2 operating system. Network bridge 3, which joins the two LANs and thus creates the WAN, is preferably configured with a PS/2 workstation employing a DOS operating system and running the Token-Ring Network Bridge Program application program, also available from IBM Corporation. It should be apparent that representative real world networks would include a significantly greater number of workstations nodes, connections and associated network protocols.

In the context of the network depicted in Fig. 1, the burden of the network administrator is to configure each of the workstations by prescribing and individually loading parameters such as node name, node operating system type, node machine type, node address, and available communication protocols suitable to accomplish the defined database requester, LAN requester, database server, LAN server or network bridge functions attributed to such workstation node within the network. As the number and diversity of the workstations and functions increase, the complexity of the network and appropriate configuration definition increase exponentially. As the variety of hardware types, operating systems, protocols and modes of operation increase, menu driven tabulated entry of WAN information is error prone even with the assistance of an expert system. In part this can be attributed to the fact that the network administrator is not provided with a dynamically responsive visual representation of the interactions between network nodes, connections, protocols and modes of operation.

The present invention introduces the use of graphical representation to define network elements in the course of deriving configuration parameters. First, workstations within the network are graphically depicted as nodes having prescribed hardware operating system resources, and communication

features. The graphically depicted connection of the nodes is overlaid, but only following a validation that the selected connections are functionally compatible with the previously specified node characteristics. For instance, and with reference to Fig. 1, the absence of a LAN server operating system in node 7 would preclude the designation of workstation 7 as a LAN server to workstation 4. Node 7 can still have the resources to provide database server functions for workstations 4 and 6.

Fig. 2 depicts an early stage in a preferred use of the invention. The illustration presents an image as would appear on a video display of the workstation used by the network administrator. The screen includes a workspace pane, generally at 8, a workstation/communication link device/data storage device selection pane, generally at 9, and a network configuration and protocol definition pane, generally at 11.

The depiction in Fig. 2 also includes a window 12 overlapping the workspace, node selection, and connection selection panes. Window 12 is the dialog window associated with workstation 13, a workstation which was selected from the choices in pane 9 and placed in workspace 8 for purposes of specifying one node of a network. Note that the node dialog window 12 is used to specify the characteristics of the node in terms of machine type, node type and data link card (DLC) capability. As embodied, the dialog window 12 provides for name and address defaults together with resources for describing two distinct data link cards.

The invention is preferably practised using a PS/2 workstation having an OS/2 operating system and an IBM brand mouse pointing and control device. Using such mouse, the network administrator selects the workstation icon 13 from pane 9 and places it into work space 8 to indicate a node in the network. Once the dialog information for window 12 has been entered by the administrator, the functional characteristics of node 13 are established.

Fig. 3 illustrates the image of the screen at a later stage in the definition of the network. At this stage an additional workstation 14 as well as database server 16 have been added to the network being defined. Fig. 3 also illustrates the commencement of a connection to be defined between workstation 14 and database server 16. A connection dialog window is not necessary in that the connection parameters are derivable by matching the connection network selected from pane 11 to the link card capabilities ascribed to each workstation node. The three node network depicted in Fig. 4 corresponds to the token-ring LAN identified at 1 in Fig. 1.

Pane 9 in Fig. 4 includes icons suitable to select an OS/2 operating system database requester workstation 17, an OS/2 operating system database server workstation 18, an OS/2 operating system database requester and server workstation 19, a DOS database requester workstation 21, an OS/2 or DOS operating

system requester (whichever is booted) workstation 22, a DOS requester with OS/2 operating system database server workstation 23, an OS/2 operating system requester and server with DOS requester workstation 24, and a "no function" overlay 26. The "no function" overlay icon identifies nodes without specific functionality in the network mode, e.g., communication or database, being defined. Such a diversity of node capability alone suggests a monumental effort for a network administrator not having the resources of the present invention.

The communication protocols available to link the node workstations are similarly diverse. The icons representing the various forms of connection protocol are depicted in pane 11 of Fig. 4. Icon 27 represents a no connection mode of operation, and invokes the mode use when selecting and dragging node icons from pane 9 into workspace pane 8. Connection icon 28 represents a SQL LOO communication LAN. The APPC (advance program to program communication) network represented by icon 29 corresponds to an IBM Corporation SNA communication network. The network of icon 31 represents the combined capability of the APPC and the SQL LOO protocols. Icon 32 corresponds to a netbios network, while network icon 33 represents a network combining SQL LOO with netbios. Icon 34 represents a network having APPC combined with netbios. Icon 36 represents the relatively all-inclusive combination of APPC, SQL LOO, and netbios protocol capability network. Again, it should be clearly evident that a network administrator is burdened with an inordinate selection not only as to the node functions but now also as to the media of connection and communication between the nodes.

According to the preferred system and method of the present invention, the administrator selects icons representing diverse workstation capabilities and interconnects such workstation nodes by selecting communication protocols. The nodes and connections are graphically depicted by icons and connecting lines or arrow patterns. The network can be manipulated as needed and is particularized by dialog windows with broad default capability. As depicted in Fig. 5, by the presence of window 37, the network configuration information can be stored and subsequently recalled for selecting refinement. The invention also contemplates a spreadsheet interface for very large networks, to permit easy replication of corresponding node functions and connection protocols. Direct transformation between spreadsheet parameters and graphical representations is readily accomplished by known transformation programs and methods.

As a further refinement of the invention, the node and connection characteristics are preferably validated at the time they are specified in the workstation used by the network administrator. Such validation will likely include a comparison of workstation resources and network requirements, a confirmation of

uniqueness in node addresses and names, a verification of consistency between machine types and node functions ascribed thereto, and a comparison of connection protocols to workstation card functionality. Systematic and automated validation avoids the common prior experience of discovering configuration errors after configuring all the workstations and enabling the network.

Preferably validation extends to the whole of the network, thereby including all nodes and connections. Validation should be performed at the earliest opportunity, e.g., by validating the structure of a node when the node name is defined or by validating that two nodes can communicate with a given protocol when the connection is defined. Thus, the validation process is distributed among the operations which can be performed and invoked when first feasible. Validation also applies to the generation of configuration files, performed to ensure that an installation would be successful if undertaken.

The invention also contemplates the creation and ensuing distribution of the configuration files to the respective node workstations. The comprehensive definition of the complete network, including a wide area network, allows for the immediate generation of configuration files for each of the node workstations. Files are related to workstation directories. In a network having a requester/server capability, the present program and process contemplates the automated and direct distribution of configuration files from the workstation of the network administrator. In the absence of such LAN requester/server capability, floppy disks are generated for each network workstation. Thereafter, installation into each workstation becomes fairly mundane.

The network topology storage and recollection feature of the present invention provides the network administrator with the resources to update the network as changes occur in the node functions or connection protocols. New configuration files are thereafter installed manually or via the LAN requester/server distribution method described above. The invention contemplates that such updates be selectively limited to only those of the workstations within the network which have had configuration changes. Again, automated comparison in the context of exceptional workstation and connection protocol diversity reduces reconfiguration delays and the likelihood of errors.

Flow diagrams representing the dominant features of a program to implement the method to which the invention pertains are depicted in the succession of Figs. 6-20. The letter "A" within a circle symbolizes a program state in which a user input is being sought. Text adjacent such symbols in a starting location describes the command provided by the user to initiate the ensuing operation. Such commands are derivatives of the menus appearing at the headings of the

 - A. If data is OK...
1. Change the option values.
 - O. Save options menu item:
 1. Write options to options file.
 - P. Restore options menu item:
 1. Read in and change options from options file.
 - Q. Drag a node in the right pane:
 1. If in a connection mode...
 - A. Draw a rubber band line.
 - B. If end location is in a different node...
1. If connection is valid...
 - A. Make and draw the connection.
 2. Else...
 - A. Drag node to new location.
 - B. Fix up screen image.
 - R. Double click a node/connection in right pane:
 1. If in Wide Area Network View and click on a node...
 - A. Switch to a view of the selected node.
 2. Else...
 - A. Put up modify node/connection dialog.
 - B. If data is changed and is valid...
1. Modify node/connection.
2. Change memory/screen image.
 - S. Modify menu item:
 1. Goto item R.2.A
 - T. Copy menu item:
 1. If current item is a node...
 - A. Put up the copy node dialog.
 - B. If data entered OK...
1. If all data is auto defaulted...
 - A. Create the copies and connections.
 - B. Update the screen and memory.

2. Else...

A. Put up one dialog for each copy...

B. If data entered is valid...

1. Create that copy in memory and on screen.

END PROGRAM

The present invention provides a network administrator, or one of like responsibility, with the resources for graphically defining and configuring a network, including sub-networks thereof, each composed of multiple nodes and connection paths. The respective nodes and connection paths are capable of exhibiting selectively diverse functionality. The network can be validated during design and subject to automated distribution as configuration files to respective network workstations. The network topology can be retained for subsequent revision and is subject to individualized configuration by mode, such as communication and database.

Though the invention has been described and illustrated by way of specific embodiments, the invention should be understood to encompass the full scope of any structures and practices defined by the claims set forth hereinafter.

Claims

1. A computer system for defining the configuration of a network, comprising:
 - means for graphically representing a first network of three or more nodes by defining first network objects for the nodes;
 - means for graphically defining connections to relate the first network objects; and
 - means for automatically generating parameters to configure a physical network as defined by the network objects and connections.
2. The system recited in Claim 1, further comprising means for validating connections by comparing attributes of defined network objects.
3. The system recited in Claim 1 or 2, further comprising means for distributing the generated configuration parameters to physical systems corresponding to the network objects.
4. The system recited in Claim 1, 2 or 3, wherein the means for graphically representing network objects and the means for graphically defining connections include means for displaying on a video display icons representing requester/server devices and connection protocols.
5. The system recited in Claim 4, wherein the requester/server devices are workstations in a

data processing network.

6. The system recited in any preceding Claim, further comprising:
 - means for graphically representing a second network of three or more nodes substantially coextensive with the first network;
 - means for defining second network objects for selected network nodes; and
 - means for graphically defining connections between selected second network objects.
7. The system recited in Claim 6, further comprising means for validating connections by comparing attributes of said second network objects.
8. The system recited in Claim 6 or 7, further comprising means for generating and distributing configuration parameters to physical systems corresponding to said second network objects.
9. The system recited in any of Claims 6 to 8, wherein the means for graphically representing said second network objects and the means for graphically defining connections include means for displaying on a video display icons representing requester/server devices and connection protocols.
10. The system recited in Claim 9, wherein the requester/server devices are workstations in a data processing network.
11. A method of generating configuration parameters for a network of workstations, comprising the steps of:
 - generating functional representations of three or more first network objects on a graphical video display;
 - generating functional representations of connections relating the first network objects on the video display;
 - generating configuration parameters to configure a physical network as defined by the combination of network objects and connections; and
 - distributing the configuration parameters to the respective network objects in a physical network.
12. The method recited in Claim 11, further comprising the step of:
 - generating in a second functional mode a second set of network objects and connections corresponding substantially to the first network objects and connections.
13. A system for configuring a network of multiple ter-

minals, comprising:
 workstation means for graphically depicting a network of three or more objects;
 workstation means for graphically depicting connections relating the network objects;
 means for a user to interactively manipulate the objects and connections depicted by the workstation; and
 means for deriving configuration parameters from combined depictions having objects and connections.

14. The system recited in Claim 13, further comprising means for distributing configuration parameters to physical systems corresponding to the network objects.
